

MICROSTRUCTURED SCREEN WITH LIGHT ABSORBING MATERIAL AND METHOD OF MANUFACTURING

CROSS-REFERENCE TO RELATED APPLICATION(S)

5 This application incorporates by reference co-pending applications serial no. _____, filed _____, entitled "Composition for Microstructured Screens" by Peter M. Olofson et al. and serial no. _____, filed _____, entitled "Microstructured Screen and Method of Manufacturing Using Coextrusion" by Kathryn M. Spurgeon et al.

10 BACKGROUND OF THE INVENTION

The present invention is directed generally to methods for manufacturing a rear projection screen and the resulting screen. More particularly, the invention relates to a rear projection screen that incorporates totally internally reflecting structures to disperse the light passing through the screen.

15 Rear projection screens are generally designed to transmit an image projected onto the rear of the screen into a viewing space. The viewing space of the projection system may be relatively large (e.g., rear projection televisions), or relatively small (e.g., rear projection data monitors). The performance of a rear projection screen can be described in terms of various characteristics of the screen.

20 Typical screen characteristics used to describe a screen's performance include gain, viewing angle, resolution, contrast, the presence of undesirable artifacts such as color and speckle, and the like.

25 It is generally desirable to have a rear projection screen that has high resolution, high contrast and a large gain. It is also desirable that the screen spread the light over a large viewing space. Unfortunately, as one screen characteristic is improved, one or more other screen characteristics often degrade. For example, the horizontal viewing angle may be changed in order to accommodate viewers positioned at a wide range of positions relative to the screen. However, increasing the horizontal viewing angle may also result in increasing the vertical viewing angle beyond what is necessary for the particular application, and so the overall

screen gain is reduced. As a result, certain tradeoffs are made in screen characteristics and performance in order to produce a screen that has acceptable overall performance for the particular rear projection display application.

In U.S. Patent No. 6,417,966, incorporated herein by reference, 5 Moshrefzadeh et al. disclose a screen having reflecting surfaces disposed so as to reflect light passing therethrough into at least one dispersion plane. The screen thereby permits asymmetric dispersion of image light in a rear projection system and allows the light to be selectively directed towards the viewer. Moshrefzadeh et al. also teach methods for manufacturing the screen, including combinations of 10 steps using casting and curing processes, coating techniques, planarization methods, and removing overcoating materials.

BRIEF SUMMARY OF THE INVENTION

The present invention is a simple and economical method for manufacturing 15 high-performance rear projection screens with internal reflection, and such projection screens. A light dispersing film for a screen has a light transmitting substrate and a plurality of light diffusive structures disposed on the substrate. A light absorbing material at least partially fills cavities between the light diffusive structures. A method of forming a light dispersing film includes providing a light transmitting substrate having a plurality of light diffusive structures disposed thereon, the structures defining a plurality of cavities therebetween, and at least 20 partially filling the cavities with a light absorbing material.

BRIEF DESCRIPTION OF THE DRAWINGS

The present invention will be further explained with references to the drawing figures below, wherein like structure is referred to by like numerals 25 throughout the several views.

FIG. 1 is a side elevation view of a microrib screen structure.

FIG. 2 is a diagram of one embodiment of a method of the present invention for producing the structure of FIG. 1.

FIG. 3 is a side elevation view of the structure of FIG. 1 filled with light-absorbing material.

FIG. 4 one method of the present invention for filling the structure of FIG. 1 to produce the structure of FIG. 3.

5 FIG. 5A is a side elevation view of one embodiment of a screen produced by the method of FIG. 4.

FIG. 5B is a side elevation view of a second embodiment of a screen produced by the method of FIG. 4.

10 FIG. 6 is a graph illustrating screen performance based on a variety of black adhesive formulations.

While the above-identified drawing figures set forth several embodiments of the invention, other embodiments are also contemplated. This disclosure presents illustrative embodiments of the present invention by way of representation and not limitation. Numerous other modifications and embodiments can be devised 15 by those skilled in the art which fall within the scope of spirit of the principles of this invention. The drawing figures are not drawn to scale.

Moreover, while the embodiments are referred to by the designations "first," "second," "third," etc., it is to be understood that these descriptions are bestowed for convenience of reference and do not imply an order of preference. The 20 designations are presented merely to distinguish between different embodiments for purposes of clarity.

DETAILED DESCRIPTION

FIG. 1 is a side elevation view of a microrib screen structure. Variations of the illustrated embodiments can be utilized for front projection and other screen 25 applications, but they will be described primarily with reference to rear projection screen applications for the purposes of this disclosure. Microrib structure 20 includes a light transmitting base substrate 22 and microstructured diffusive ribs 24. The term "microstructured" includes features having characteristic dimensions

measured in micrometers (μm) or smaller units. In general, microstructured features may have characteristic dimensions ranging from less than $0.01\ \mu\text{m}$ to more than $100\ \mu\text{m}$. What constitutes a characteristic dimension of a feature depends on the type of feature. Examples include the width of trough-like features in a surface, the 5 height of post-like protrusions on a surface, and the radius of curvature at the point of sharp protrusions or indentations on a surface. Thus, even a macroscopic feature can be said to be microstructured if a characteristic dimension of the feature has dimensions with sub-micrometer tolerances.

In one exemplary embodiment, linear ribs or microribs 24 are formed of an 10 optical-grade host material such as a resin; in particular, the resin incorporates light scattering particles such as beads so that ribs 24 act as a bulk diffuser. A sufficiently high aspect ratio is chosen for the rib geometry in order to induce total internal reflection (TIR) in the microrib structure 20. The loading of the light scattering particles within the resin is chosen to control optical properties such as 15 gain and view angle of the screen. A material such as a resin with a high refractive index (RI) is generally chosen for diffusive ribs 24. In this application, the RI of a rib 24 refers to the RI of the host material. Examples of suitable host materials for light diffusive ribs 24 include polymers such as modified acrylics, polycarbonate, polystyrene, polyester, polyolefin, polypropylene, and other optical polymers 20 preferably having a refractive index equal to or greater than about 1.50. In the embodiment shown in FIG. 1, the light diffusive ribs 24 are separated by V-shaped cavities or grooves 26. While light diffusive structures 24 are described in an exemplary embodiment as ribs that extend across substantially the entire width of base substrate 22, it is also contemplated that the structures 24, in an alternative 25 embodiment, form discrete peaks that can be arranged upon base substrate 22 in a staggered, or “checkerboard” pattern, for example. In an exemplary embodiment, each structure 24 has a base 23 and a plurality of walls 25 which narrow the structure 24 as walls 25 extend from base 23.

FIG. 2 is a diagram of one embodiment of a method for producing the structure of FIG. 1. A process for producing the screen structure 20 of FIG. 1 includes a microreplication process 28 to produce diffusive ribs 24 on base substrate 22. The term "microreplication" includes a process whereby microstructured features are imparted from a master or a mold onto an article. The master is provided with a microstructure, for example by micro-machining techniques such as diamond turning, laser ablation or photolithography. The surface or surfaces of the master having the microstructure may be covered with a hardenable material so that when the material is hardened, an article is formed that has a negative replica of the desired microstructured features. The microreplication may be accomplished using rolls, belts, and other apparatuses known in the art. Microreplication can be accomplished by techniques including but not limited to extruding, embossing, radiation curing and injection molding. Microreplication process 28 uses substrate unwind station 30, resin coating station 32, precision nip roll 34, microstructured cylinder 36, ultraviolet lamp 38, precision nip roll 40 and film rewind 42.

Base substrate 22 is first unwound from substrate unwind station 30. Base substrate 22 is guided to pass into microreplication process 28 resin coating station 32, where the base is coated with a high refractive index resin incorporating light scattering particles. The base substrate 22 and light diffusive material coating are pressed by precision nip roll 34 against microstructured cylinder 36 to impart the ribbed structure to the light diffusive material. The cast structure is then cured by ultraviolet lamp 38 and microribbed structure 20 emerges from precision nip roll 40, resulting in the monolithic structure illustrated in FIG. 1. A cured microrib structure 20 emerges from precision nip roll 40 to be wound upon film rewind 42.

FIG. 3 is a side elevation view of the structure of FIG. 1 filled with light-absorbing material 46. Embedded microstructured film 44 includes filling material 46. Material 46 typically incorporates a black pigment or dye to absorb ambient

light and improve contrast in the final screen construction. Optical material 46 has a low refractive index so that a relatively high difference in refractive index exists between light absorbing material 46 and the material composing light diffusive ribs 24. A refractive index difference of at least about 0.06 is desired. Such a difference induces efficient internal reflection and high screen performance. Internally reflecting surfaces 48 are formed by the interfaces between light diffusive ribs 24 and light absorbing material 46. In one exemplary embodiment, front surface 50 of embedded microstructured film 44 is a smooth or slightly matte surface with minimal land on the rib top surfaces 52. Totally internally reflecting surfaces 48 disperse light through optically transmitting areas 52 of front surface 50. Front surface 50 preferably has a matte surface finish that assists in scattering the light propagating therethrough.

FIG. 4 is a side elevation view of one method of the present invention for filling the structure of FIG. 1 to produce the structure 44 of FIG. 3. In one embodiment of the method of the present invention, microrib structure 20 is formed by the microreplication process 28 discussed above with respect to FIG. 2 to impart light diffusive ribs 24 having V-shaped grooves 26 onto base structure 22. The process shown in FIG. 4 uses a light absorbing adhesive 56 which possesses both light absorbing and adhesive functionalities. The term “adhesive” used with reference to light absorbing adhesive 56 need not be an adhesive in the normal sense, but needs only to have bonding capabilities with light diffusive ribs 24, and also to shielding substrate or shield 54 if used. By combining the light absorption and adhesive functions in one material, savings in materials and manufacturing steps are obtained. Light absorbing adhesive 56 is disposed on rear surface 58 of shield 54. Shield 54, with light absorbing adhesive 56 disposed thereon, is brought together with microrib structure 20. As shown by arrow 59, for example, shield 54 and microrib structure 20 are laminated together.

The thickness of light transmitting base film 22 can be chosen to meet the requirements of each particular application. For example, a thin base film with a thickness of about 0.127 mm (5 mils) to about 0.254 mm (10 mils) can be chosen to provide for ease of manufacturing; alternatively, a thick film with a thickness of 5 about 0.508 mm (20 mils) to about 1.016 mm (40 mils) can be chosen to provide additional product stiffness. Suitable materials include polycarbonate, polyester, acrylic and vinyl films, for example. In one exemplary embodiment, back surface 62 of base substrate 22 has a matte finish to reduce specular reflection back into the imaging system.

10 Light transmitting shield 54 is a protective layer that can be a film or sheet made of transparent material such as acrylic, polycarbonate or glass, for example. Shield 54 functions as a protective element so that the coated microstructured film 44 is not damaged by contact. Shield 54 is an optional component, though most applications benefit greatly from this protection. Shield 54 can be made to be anti-glare (matte), anti-reflective, anti-static, anti-scratch or smudge resistant, for 15 example, through coatings, surface textures, or other means. In one embodiment, shield 54 is a 3 millimeter thick acrylic panel from Cyro Corporation with a non-glare, matte outward-facing surface. Shield 54 can also be varied to provide for different functionalities. Shield 54 can range in thickness from thin (less than about 20 0.508 mm (20 mils)) to semi-rigid (about 0.508 mm (20 mils) to about 1.016 mm (40 mils)) to rigid (greater than about 1.016 mm (40 mils)). The thicknesses of base substrate 22 and protective shield 54 can be chosen to yield a wide variety of products with these options impacting total material cost, optical functionality, and ease of processing.

25 In one exemplary embodiment, light absorbing adhesive 56 is a photopolymerizable, low refractive index material which adheres to both light diffusive ribs 24 and shield 54. In an exemplary embodiment, the refractive indices of light diffusive ribs 24 and light absorbing adhesive 56 differ enough to cause

total reflection rather than transmittance at the interface therebetween. In an exemplary embodiment, the refractive index of the microrib material of light diffusive ribs 24 varies from 1.49 for simple acrylate materials to 1.58 or higher for materials such as aromatic polycarbonates. The refractive index requirement for the 5 groove filler material 56 is, therefore, dependent on the optical properties (such as refractive index) of the microrib 24 material. For the high refractive index microrib materials, such as polycarbonate, commercially available photolaminating adhesives may be adequate. Exemplary adhesives 56 have a RI of less than about 1.50. Particularly suitable adhesives 56 have a RI of less than about 1.45. In some 10 embodiments, adhesive 56 is a pigmented blend of one or more of the following components: urethane acrylate oligomers; substituted acrylate, diacrylate, and triacrylate monomers; fluorinated acrylates; perfluoroalkylsulfonamidoalkyl acrylates; acrylated silicones; acrylated silicone polyureas, and UV or visible light activated photoinitiators.

15 If the viscosity of the groove filler adhesive 56 is too low, it will flow during the groove filling process. This can waste material, give nonuniform thickness, and contaminate the process equipment. If the viscosity is too high, filling the grooves 24 can be a slow, difficult process and the possibility of introducing bubbles (optical defects) increases significantly. While 20 photolamination can be accomplished with fluids having viscosities as low as about 150 centipoises, many processes can benefit from a viscosity of at least about 400 centipoises before polymerization. While viscosities as high as about 5,000 centipoises before polymerization can be used, viscosities no higher than about 1,500 centipoises before polymerization are especially suitable for reasonable 25 process speed and bubble-free coatings.

A standard measure of adhesion between substrates and coatings is the amount of force required to separate them, known as the peel force. The peel force of a system containing excellent interfacial adhesion at the interface between layers

will be very high. While peel force strength of at least about 35.71 kg/m (2 pounds/inch) is probably adequate between polycarbonate diffusive ribs 24 and light absorbing adhesive 56, it is more desirable to have peel force of at least about 71.42 kg/m (4 pounds/inch). This high peel force should be maintained under 5 environmental test conditions of high temperature and humidity. Adequate adhesion may be achieved by modification of the substrate surfaces by treatment, such as with corona discharge or plasma, or priming; it is preferred, however, that the adhesive 56 adhere to the light diffusive ribs 24 and shield 54, if used, without the necessity of surface modification.

10 One suitable embodiment of light absorbing adhesive 56 is constructed by warming the following resin components to about 70°C (158°F) to lower the viscosity sufficiently to allow for agitation: 16.0 g aliphatic urethane acrylate oligomer; 19.0 g ethoxyethoxyethyl acrylate; 5.5 g hexanediol diacrylate; 5.0 g tetrahydrofurfuryl acrylate; 44.5 g N-methyl-perfluorobutylsulfonamidoethyl acrylate; 10.0 g acryloyloxyethoxyperfluorobutane; and 1.0 g phenyl bis(2,4,6 trimethyl benzoyl) phosphine oxide photoinitiator.

15 The components are then shaken until a clear solution results. The solution is then pigmented for light absorption. One suitable pigment is carbon black; in one embodiment, the pigment is used in a concentration between about 50 ppm (parts per million) and about 20,000 ppm; in one exemplary embodiment, the pigment is used in a concentration greater than about 1000 ppm and less than about 9000 ppm. A concentration of about 3000 ppm is particularly suitable, based on 20 mass ratios of the carbon black material to the resin material. In one embodiment, the formulation is disposed onto shield 54 by a conventional method such as knife coating. The coated shield is then pressed onto microrib structure 20 as shown in FIG. 4, for example, to partially or completely fill grooves 26. Excess adhesive 56, if any, is expelled by running a rubber roller over the construction. The 25 construction is passed under a 11.81 W/mm (300 Watt/in) Fusion Systems D lamp

one or more times at about 6.1 m (20 feet) per minute. In an alternate method, the formulation may be coated directly onto the microrib structure 20, and shield 54 then adhered to the microrib structure 20 with adhesive 56 already disposed thereon. Thereafter, the steps of removing excess adhesive 56 and curing the 5 construction are the same as discussed above.

FIG. 5A is a side elevation view of one embodiment of a screen produced by the method of FIG. 4. The step of FIG. 4 can result in a completely filled structure 60. In one exemplary embodiment, light absorbing adhesive 56 has a low refractive index to produce efficient TIR within ribs 24. Light absorbing adhesive 10 56 is formulated to effectively bond diffuser ribs 24 to shield 54. Light absorbing adhesive 56 can possess low shrinkage properties to produce a cosmetically acceptable lamination result. Moreover, it is particularly suited that light absorbing adhesive 56 is curable by ultraviolet light in order to allow for convenient processing and a fast cure. In one embodiment, substrate 22 and protective shield 15 54 are individually flexible, but completely filled structure 60 is rigid.

In one embodiment, light diffusive ribs 24 are replicated from a tooling mold using a high refractive index diffuser resin, as shown in microreplication process 28 of FIG. 2. In this application, all percentages are by mass unless otherwise indicated. One suitable resin is about 79% aliphatic urethane acrylate 20 oligomer and about 19% 2-phenoxyethyl acrylate, and about 2% 2-hydroxy-2-methyl-1-phenyl-1-propanone photoinitiator. Another suitable resin is about 69% aliphatic urethane acrylate oligomer, about 29% 2-(1-naphthoxy)-ethyl acrylate and about 2% 2-hydroxy-2-methyl-1-phenyl-1-propanone photoinitiator. The resin 25 for forming ribs 24 is coated from resin coating station 32 onto substrate or base structure 22. Base structure 22 with resin thereon is molded by microstructured cylinder 36 and cured by ultraviolet (UV) lamps or electron beams 38. Typical UV cure conditions use a 23.62 W/mm (600 Watt/in) Fusion Systems D bulb system, operated at belt speeds of about 3.05 m (10 feet) to about 6.10 m (20 feet) per

minute, with one or more passes under the UV Bulb. The formed microrib structure 20 is removed from microreplication process 28, yielding a self-supporting structure.

Then, a pigmented, typically black, light absorbing adhesive 56 can be applied to a second substrate such as shield 54. One suitable light absorbing adhesive 56 is formed from a resin having about 30% "Formulation A" (the "Formulation A" having about 38.5% aliphatic urethane acrylate oligomer, about 26.9% ethoxyethoxyethyl acrylate, about 28.8% isobornyl acrylate, about 5.8% hexanediol diacrylate and about 1% α,α -diethoxyacetophenone (DEAP) photoinitiator); about 10% aliphatic urethane diacrylate; about 30% trifluoroethyl acrylate; and about 30% N-methyl-perfluorobutylsulfonamidoethyl acrylate. Another suitable light absorbing material 56 is formed from a resin having about 50% "Formulation A," discussed above, and about 50% N-methyl-perfluorobutylsulfonamidoethyl acrylate. In one exemplary embodiment, light absorbing adhesive 56 contains a pigment such as carbon black. In one exemplary embodiment, the pigment is used in a concentration between about 50 ppm (parts per million) and about 20,000 ppm. In one exemplary embodiment, the pigment is used in a concentration greater than about 1,000 ppm and less than about 9,000 ppm. A concentration of about 3,000 ppm is particularly suitable, based on mass ratios of the carbon black material to the adhesive material.

Light absorbing adhesive 56 is applied to a second substrate such as shield 54 in sufficient quantity to completely fill diffuser ribs 24, allowing a slight excess to ensure complete fill, in the lamination method illustrated in FIG. 4. The excess adhesive squeezes out of completely filled structure 60 upon lamination. Completely filled structure 60 is then exposed to radiation under conditions similar to those discussed above for microreplication process 28. The exposure can, for example, result in a partial or complete polymerization of the material. After at

least partial polymerization, light absorbing adhesive 56 is a copolymer of its components.

FIG. 5B is a side elevation view of a second embodiment of a screen produced by the method of FIG. 4. When a small thickness or amount of light absorbing adhesive 56 is used in the step illustrated in FIG. 4, partially filled structure 64 results. In partially filled structure 64, air gaps 66 are left in V-shaped grooves 26. A benefit of air gap 66 is that the low refractive index air fills the rib grooves 26 and creates a large refractive index difference between the grooves 26 and the light diffusive ribs 24, further enhancing “TIR efficiency”. Because the refractive index of air is 1.0, the difference in refractive index between air gap 66 and light diffusive ribs 24 is usually greater than about 0.5. Because air gap 66 creates the bulk of the diffuser rib interface, light absorbing adhesive 56 need not possess as low a refractive index as when the ribs are completely filled in structure 60. This allows for the selection of an adhesive 56 to optimize other important properties, such as low shrinkage and high peel strength adhesion, for example. Since the adhesive contact area between light absorbing adhesive 56 and diffuser ribs 24 is smaller, light absorbing adhesive 56 may possess greater adhesive properties in partially filled structure 64 than completely filled structure 60. In one embodiment, substrate 22 and protective shield 54 are individually flexible, but partially filled structure 64 is rigid.

In both completely filled structure 60 and partially filled structure 64, the level of light absorbing material used in light absorbing adhesive 56 is chosen based on the desired amount of contrast enhancement and ambient light absorption. The light absorbing material in an exemplary embodiment is a black pigment such as carbon black. In completely filled structure 60, the black pigment concentration can be relatively low and yet yield an acceptable total fixed absorbence, or optical density value, because the thickness of the layer of light absorbing adhesive 56 is large. A suitable loading concentration of pigment such as carbon black in

completely filled structure 60 in one embodiment is between about 50 ppm (parts per million) and about 20,000 ppm. In an exemplary embodiment, the concentration is greater than about 1000 ppm and less than about 9000 ppm. A concentration of about 3000 ppm is particularly suitable, based on mass ratios of 5 the carbon black material to the adhesive material. However, in partially filled structure 64, the coating thickness is small; therefore, the black pigment concentration must be larger to yield the same optical density. In the latter case, the ambient light absorption is larger per unit of coating thickness than in the former case. A suitable loading concentration of pigment such as carbon black in partially 10 filled structure 64 in one embodiment is between about 50 ppm and about 20,000 ppm. In an exemplary embodiment, the concentration is greater than about 5,000 ppm and less than about 10,000 ppm, based on mass ratios of the carbon black material to the adhesive material.

A challenge in both completely filled structure 60 and partially filled 15 structure 64 is the removal of excess adhesive 56 from front surface 50 of diffuser ribs 24 during lamination. If all of the light absorbing adhesive 56 is not removed from front surface 50 of the diffuser ribs 24 during lamination, some image light can be lost due to absorption during TIR transmission. In a partially filled structure 64 with more highly pigmented adhesive 56, more loss of image light can occur for 20 the same residual black layer thickness.

FIG. 6 is a graph illustrating screen performance based on a variety of black adhesive formulations. One way of gauging screen performance is by plotting the horizontal gain curve as a function of viewing angle. The plotted curves describe the brightness of the screen perceived by a viewer as the viewer moves sideways 25 away from the center of the screen. “TIR efficiency” relates to the range of incident light angles that result in total internal reflection; the greater the range, the higher the efficiency. Reflection from the rib 24 sides can produce a local maximum in the gain curve as shown. As both the TIR efficiency and RI difference increase, the

secondary peak in the gain curve (near 30 degrees horizontal viewing angle) can increase. The effect of a local maximum can be reduced or eliminated by, for example, introducing light diffusion into the projection screen. For example, ribs 24 may include particles to make the local maximum less pronounced by scattering 5 any incident light.

Curve 68 refers to a benchmark standard screen using a standard planarization technique for filling cavities 26 with light absorbing material. The benchmark standard screen has light diffusive ribs 24 formed from a resin having about 80% aliphatic urethane acrylate oligomer and about 20% 2-phenoxyethyl acrylate. Light diffusive ribs 24 have a refractive index of about 1.51. Light 10 absorbing material 46 is formed from a resin having about 60% proprietary RC709 silicone acrylate from Goldschmidt Corp., about 39% propoxylated neopentyl glycol diacrylate, and about 1% Darocur 4265 (a 1:1 blend of 2-hydroxy-2-methyl-1-phenyl-1-propanone and diphenyl (2,4,6-trimethylbenzoyl)-phosphine oxide) 15 photoinitiator with carbon black pigment in a concentration of about 3,000 ppm. Light absorbing material 46 has a refractive index of about 1.45. The RI difference between light absorbing material 46 and light diffusive ribs 24 is about 0.06. This formulation of light absorbing material 46 possesses low shrinkage characteristics, good processing properties, uniform dispersion of the black pigment, low price and 20 widespread availability.

Curve 70 refers to a screen formed by the method illustrated in Figs. 4 and 5A which shows the gain when the RI difference between diffuser ribs 24 and light absorbing adhesive 56 is less than about 0.01. The screen corresponding to curve 25 70 has light diffusive ribs 24 formed from a resin having about 80% aliphatic urethane acrylate oligomer and about 20% 2-phenoxyethyl acrylate. Light diffusive ribs 24 have a refractive index of about 1.51. Light absorbing material 56 is formed from a "Formulation A" resin having about 38.5% aliphatic urethane acrylate oligomer; about 26.9% ethoxyethoxyethyl acrylate; about 28.8% isobornyl acrylate;

about 5.8% hexanediol diacrylate; and about 1% α,α -diethoxyacetophenone (DEAP) photoinitiator. Light absorbing material 56 has a refractive index of about 1.50.

Curve 72 refers to a screen formed by the method illustrated in Figs. 4 and 5A which has increased "TIR efficiency" when a light absorbing adhesive 56 with relatively low RI is used. The screen corresponding to curve 72 has light diffusive ribs 24 formed from a resin having about 80% aliphatic urethane acrylate oligomer and about 20% 2-phenoxyethyl acrylate. Light diffusive ribs 24 have a refractive index of about 1.51. Light absorbing material 56 is formed from a resin having about 30% "Formulation A," discussed above; about 10% aliphatic urethane diacrylate; about 30% trifluoroethyl acrylate; about 30% N-methyl-perfluorobutylsulfonamidoethyl acrylate; and about 1% α,α -diethoxyacetophenone (DEAP) photoinitiator. Light absorbing adhesive 56 has a refractive index of about 1.44.

Finally, curve 74 refers to a screen formed by the method illustrated in Figs. 4 and 5A, in which the TIR efficiency is increased, where the RI difference between light absorbing adhesive 56 and light diffusive ribs 24 is about 0.08. The screen corresponding to curve 74 has light diffusive ribs 24 formed from a resin having about 70% aliphatic urethane acrylate oligomer and about 30% 2-(1-naphthoxy)-ethyl acrylate. Light diffusive ribs 24 have a refractive index of about 1.5338. Light absorbing material 46 is formed from a resin having about 50% "Formulation A," discussed above; about 50% N-methyl-perfluorobutylsulfonamidoethyl acrylate; and about 1% α,α -diethoxyacetophenone (DEAP) photoinitiator. Light absorbing material 56 has a refractive index of about 1.45.

As shown in FIG. 6, the formulation of light absorbing adhesive 56 relative to the formulation of light diffusive ribs 24 can be chosen to produce the desired screen performance characteristics. Usually, the formulations are chosen to maximize the RI difference between light absorbing adhesive 56 and light diffusive

ribs 24. It is desirable for light absorbing adhesive 56 to achieve strong adhesion to light diffusive ribs 24 and protective shield 54, possess a relatively low RI, have high mechanical strength after curing, and processability properties such as appropriate viscosity and curability by ultraviolet light. A suitable component of 5 light absorbing material 56 is an aliphatic urethane acrylate oligomer. In some embodiments, light absorbing adhesive 56 contains at least about 5 percent of an aliphatic urethane acrylate oligomer. In an exemplary embodiment, light absorbing adhesive 56 contains at least about 10 percent of an aliphatic urethane acrylate oligomer. In some embodiments, light absorbing adhesive 56 contains less than 10 about 50 percent of an aliphatic urethane acrylate oligomer. In an exemplary embodiment, light absorbing adhesive 56 contains less than about 40 percent of an aliphatic urethane acrylate oligomer. If the concentration of aliphatic urethane acrylate oligomer is too low, light absorbing adhesive 56 may not be viscous enough; if the concentration is too high, light absorbing adhesive 56 may be too 15 viscous, and the refractive index may be too high.

Another suitable component of light absorbing adhesive 56 is a low RI compatible acrylate monomer, of which ethoxyethoxyethyl acrylate is an example. In some embodiments, light absorbing adhesive 56 contains at least about 1 percent 20 of an acrylate monomer. In an exemplary embodiment, light absorbing adhesive 56 contains at least about 8 percent of an acrylate monomer. In some embodiments, light absorbing adhesive 56 contains less than about 30 percent of an acrylate monomer. In an exemplary embodiment, light absorbing adhesive 56 contains less than about 20 percent of an acrylate monomer. In an exemplary embodiment, the acrylate monomer has a low RI and serves as a solvent to enhance the compatibility 25 of the other components of light absorbing adhesive 56.

Another suitable component of light absorbing material 56 is a multifunctional acrylate monomer to add strength, of which hexanediol diacrylate is an example. In some embodiments, light absorbing adhesive 56 contains at least

about 0.1 percent of a multifunctional acrylate monomer. In an exemplary embodiment, light absorbing adhesive 56 contains at least about 1.0 percent of a multifunctional acrylate monomer. In some embodiments, light absorbing adhesive 56 contains less than about 10 percent of a multifunctional acrylate monomer. In 5 an exemplary embodiment, light absorbing adhesive 56 contains less than about 6 percent of a multifunctional acrylate monomer. The higher the functionality of the multifunctional acrylate monomer, the lower the required concentration.

The screen with "Formulation A" light absorbing adhesive 56, illustrated by curve 70, has too high a RI to provide efficient TIR. One compatible component 10 for decreasing the RI of light absorbing adhesive 56 is a perfluoroalkylsulfonamidoethyl acrylate, of which N-methyl-perfluorobutylsulfonamidoethyl acrylate is an example. In some embodiments, light absorbing adhesive 56 contains at least about 1 percent of a perfluoroalkylsulfonamidoethyl acrylate. In an exemplary embodiment, light 15 absorbing adhesive 56 contains at least about 10 percent of a perfluoroalkylsulfonamidoethyl acrylate. In some embodiments, light absorbing adhesive 56 contains less than about 70 percent of a perfluoroalkylsulfonamidoethyl acrylate. In an exemplary embodiment, light absorbing adhesive 56 contains less than about 50 percent of a 20 perfluoroalkylsulfonamidoethyl acrylate.

Where light absorbing material 56 is photopolymerized, a suitable photoinitiator is included; phenyl bis(2,4,6 trimethyl benzoyl) phosphine oxide photoinitiator and α,α -diethoxyacetophenone (DEAP) photoinitiator are examples 25 of suitable free radical photoinitiators. In some embodiments, light absorbing adhesive 56 contains at least about 0.5 percent of a photoinitiator. In an exemplary embodiment, light absorbing adhesive 56 contains about 1.0 percent of a photoinitiator. In some embodiments, light absorbing adhesive 56 contains less

than about 5 percent of a photoinitiator. In other embodiments, a thermal polymerization or redox initiator is chosen.

Although the present invention has been described with reference to exemplary embodiments, workers skilled in the art will recognize that changes may 5 be made in form and detail without departing from the spirit and scope of the invention. For example, while particular shapes for light diffusive and light absorbing structures are illustrated, it is contemplated that the structures may be formed in different shapes, incorporating additional or different planes or angles, additional edges, and curved surfaces. It is further noted that the light diffusive 10 structures on a particular substrate need not all be of the same height or shape, for example. Similarly, the light absorbing structures on a particular substrate need not all be of the same height or shape, for example. Moreover, components of the materials and processes described therein are combinable in numerous ways; only a few of those possibilities have been specifically described by way of example, 15 although all are regarded to be within the scope of the invention.
